Computational Logic

Logic Programming:

Model and Fixpoint Semantics
Towards the Model and Fixpoint Semantics

• We have seen previously the operational semantics (SLD-resolution).
• We now present the (declarative) Model Semantics:
  ◦ We define our semantic domain (Herbrand interpretations).
  ◦ We introduce the Minimal Herbrand Model.
• And the (also declarative) Fixpoint Semantics.
  ◦ We recall some basic fixpoint theory.
  ◦ Present the $T_P$ operator and the classic fixpoint semantics.
Declarative Semantics – Herbrand Base and Universe

- Given a first-order language $L$, with a non-empty set of variables, constants, function symbols, relation symbols, connectives, quantifiers, etc. and given a syntactic object $A$,

$$ground(A) = \{ A\theta | \exists \theta \in Subst, var(A\theta) = \emptyset \}$$

i.e. the set of all “ground instances” of $A$.

- Given $L$, $U_L$ (Herbrand universe) is the set of all ground terms of $L$.

- $B_L$ (Herbrand Base) is the set of all ground atoms of $L$.

- Similarly, for the language $L_P$ associated with a given program $P$ we define $U_P$, and $B_P$. 
Declarative Semantics – Herbrand Base and Universe (example)

- Program:

\[
P = \{ \, p(f(X)) \leftarrow p(X). \\
p(a). \\
q(a). \\
q(b). \, \}
\]

- Herbrand universe:

\[
U_P = \{a, b, f(a), f(b), f(f(a)), f(f(b)), \ldots\}
\]

- Herbrand base:

\[
B_P = \{p(a), p(b), q(a), q(b), p(f(a)), p(f(b)), q(f(a)), \ldots\}
\]
Herbrand Interpretations and Models

- A **Herbrand Interpretation** is a subset of $B_L$, i.e. the set of all Herbrand interpretations $I_L = \wp(B_L)$.
  (Note that $I_L$ forms a complete lattice under $\subseteq$ – important for fixpoint operations to be introduced later).

- In previous example: $P = \{ p(f(X)) \leftarrow p(X). \ p(a). \ q(a). \ q(b). \ \}$
  $U_P = \{ a, b, f(a), f(b), f(f(a)), f(f(b)), \ldots \}$
  $B_P = \{ p(a), p(b), q(a), q(b), p(f(a)), p(f(b)), q(f(a)), \ldots \}$
  $I_P = \text{all subsets of } B_P$

- A **Herbrand Model** is a Herbrand interpretation which contains all logical consequences of the program.

- The **Minimal Herbrand Model** $H_P$ is the smallest Herbrand interpretation which contains all logical consequences of the program. (Theorem: it is unique.)

- Example:
  $H_P = \{ q(a), q(b), p(a), p(f(a)), p(f(f(a))), \ldots \}$
• **Declarative semantics of a logic program** $P$:
  the set of ground facts which are logical consequences of the program (i.e., $HP$).
  (i.e., the *Minimal Herbrand* model (or “least model”) of $P$).

• **Intended meaning of a logic program** $P$:
  the set $I$ of ground facts that the user expects to be logical consequences of the program.

• A logic program is **correct** if $HP \subseteq I$.

• A logic program is **complete** if $I \subseteq HP$.

• Example:
  
  father(john,peter).
  father(john,mary).
  mother(mary,mike).
  grandfather(X,Y) ← father(X,Z), father(Z,Y).

  with the usual intended meaning is **correct** but **incomplete**.
Towards a Fixpoint Semantics for LP – Fixpoint Basics

- A **fixpoint** for an operator $T : X \rightarrow X$ is an element of $x \in X$ such that $x = T(x)$.
- If $X$ is a poset, $T$ is monotonic if $\forall x, y \in X, x \leq y \Rightarrow T(x) \leq T(y)$
- If $X$ is a complete lattice and $T$ is monotonic the set of fixpoints of $T$ is also a complete lattice [Tarski]
- The least element of the lattice is the **least fixpoint** of $T$, denoted $\text{lfp } T$
- Powers of a monotonic operator (successive applications):
  
  \[
  T \uparrow 0(x) = x \\
  T \uparrow n(x) = T(T \uparrow (n-1)(x))(n \text{ is a successor ordinal}) \\
  T \uparrow \omega(x) = \bigcup \{T \uparrow n(x) | n < \omega\}
  \]

  We abbreviate $T \uparrow \alpha(\bot)$ as $T \uparrow \alpha$

- There is some $\omega$ such that $T \uparrow \omega = \text{lfp } T$. The sequence $T \uparrow 0, T \uparrow 1, ..., \text{lfp } T$ is the **Kleene sequence** for $T$
- In a finite lattice the Kleene sequence for a monotonic operator $T$ is finite
Towards a Fixpoint Semantics for LP – Fixpoint Basics (Contd.)

- A subset $Y$ of a poset $X$ is an (ascending) chain iff $\forall y, y' \in Y, y \leq y' \lor y' \leq y$
- A complete lattice $X$ is *ascending chain finite* (or *Noetherian*) if all ascending chains are finite
- In an ascending chain finite lattice the Kleene sequence for a monotonic operator $T$ is finite

ascending_chain finite
A Fixpoint Semantics for Logic Programs

- **Semantic domain**: $I_L = \wp(B_L)$.
- I.e., the elements of the semantic domain and interpretations (subsets of the Herbrand base).
- **Semantic operator** (defined on programs): the *immediate consequences operator*, $T_P$:
  - $T_P$ is a mapping: $T_P : I_P \rightarrow I_P$ defined by:
    $$T_P(I) = \{ A \in B_P \mid \exists C \in \text{ground}(P), C = A \leftarrow L_1, \ldots, L_n \text{ and } L_1, \ldots L_n \in I \}$$
    (in particular, if $(A \leftarrow) \in P$, then every element of $\text{ground}(A)$ is in $T_P(I)$, $\forall I$).
- $T_P$ is monotonic, so:
  - it has a least fixpoint $I^*$ so that $T_P(I^*) = I^*$,
  - this fixpoint can be obtained by applying $T_P$ iteratively starting from the bottom element of the lattice (the empty interpretation).
A Fixpoint Semantics for Logic Programs: Example 1 (finite)

\[
P = \{ \begin{align*}
p(X, a) & \leftarrow q(X). \\
p(X, Y) & \leftarrow q(X), r(Y). \\
q(a). & \\
q(b). & \\
q(b). & \end{align*} \}
\]

\[
U_P = \{ a, b, c \}
\]

\[
B_P = \{ \begin{align*}
p(a, a), & p(a, b), p(a, c), p(b, a), p(b, b), p(b, c), p(c, a), p(c, b), p(c, c), \\
q(a), & q(b), q(c), \\
r(a), & r(b), r(c) \end{align*} \}
\]

\[
I_P = \text{all subsets of } B_P
\]

\[
H_P = \{ q(a), q(b), r(b), r(c), p(a, a), p(b, a), p(a, b), p(b, b), p(a, c), p(b, c) \}
\]

\[
T_P \uparrow 0 = \{ q(a), q(b), r(b), r(c) \}
\]

\[
T_P \uparrow 1 = \{ q(a), q(b), r(b), r(c) \} \cup \{ p(a, a), p(b, a), p(a, b), p(b, b), p(a, c), p(b, c) \}
\]

\[
T_P \uparrow 2 = T_P \uparrow 1 = \text{lfp}(T_P) = H_P
\]
A Fixpoint Semantics for Logic Programs: Example 2 (infinite)

\[ P = \{ \ p(f(X)) \leftarrow p(X). \ 
\ p(a). \ 
\ q(a). \ 
\ q(b). \ \} \]

\[ U_P = \{ a, b, f(a), f(b), f(f(a)), f(f(b)), \ldots \} \]
\[ B_P = \{ p(a), p(b), q(a), q(b), p(f(a)), p(f(b)), q(f(a)), \ldots \} \]
\[ I_P = \text{all subsets of } B_P \]
\[ H_P = \{ q(a), q(b), p(a) \} \cup \{ p(f^n(a)) \mid n \in \mathbb{N} \} \]
where we define \( f^n(a) \) to be \( f \) nested \( n \) times and then applied to \( a \).
(i.e., \( q(a), q(b), p(a), p(f(a)), p(f(f(a))), p(f(f(f(a)))), \ldots \))

\[ T_P \uparrow 0 = \{ p(a), q(a), q(b) \} \]
\[ T_P \uparrow 1 = \{ p(a), q(a), q(b), p(f(a)) \} \]
\[ T_P \uparrow 2 = \{ p(a), q(a), q(b), p(f(a)), p(f(f(a))) \} \]
\[ \ldots \]
\[ T_P \uparrow \omega = H_P \]
Example:

\[ P = \{ \text{nat}(0). \]
\[ \text{nat}(s(X)) \leftarrow \text{nat}(X). \]
\[ \text{sum}(0, X, X). \]
\[ \text{sum}(s(X), Y, s(Z)) \leftarrow \text{sum}(X, Y, Z). \} \]

\[ U_P = \{0\} \cup \{s(x) \mid x \in U_P\} \]

(i.e., \{0, s(0), s(s(0)), s(s(s(0))), \ldots\}).

\[ B_P = \{\text{nat}(x) \mid x \in U_P\} \cup \{\text{sum}(x, y, z) \mid x, y, z \in U_P\} \]

(i.e., \{nat(0), nat(s(0)), nat(s(s(0))), \ldots\} \cup
\{sum(0, 0, 0), sum(s(0), 0, 0), sum(0, s(0), 0), sum(0, 0, s(0)), \ldots\}).
Constructing the least fixpoint of the $T_P$ operator:

$T_P \uparrow 0 = \{ \text{nat}(0) \} \cup \{ \text{sum}(0, x, x) \mid x \in U_P \}$

$T_P \uparrow 1 = T_P \uparrow 0 \cup \{ \text{nat}(s(0)) \}$

$\quad \cup \{ \text{sum}(s(0), y, s(y)) \mid y \in U_P \}$

$T_P \uparrow 2 = T_P \uparrow 1 \cup \{ \text{nat}(s(s(0))) \}$

$\quad \cup \{ \text{sum}(s(s(0)), y, s(s(y))) \mid y \in U_P \}$

$T_P \uparrow 3 = T_P \uparrow 2 \cup \{ \text{nat}(s(s(s(0)))) \}$

$\quad \cup \{ \text{sum}(s(s(s(0))), y, s(s(s(y)))) \mid y \in U_P \}$

$\ldots$

$T_P \uparrow \omega = \{ \text{nat}(x) \mid x \in U_P \} \cup$

$\{ \text{sum}(s^n(0), y, s^n(y)) \mid y \in U_P \land n \in \mathbb{N} \}$

where we define $s^x(y)$ to be $s$ nested $x$ times and then applied to $y$.  

Semantics – Equivalences

- (Characterization Theorem) [Van Emden and Kowalski]
  A program $P$ has a Herbrand model $H_P$ such that:
  - $H_P$ is the least Herbrand Model of $P$.
  - $H_P$ is the least fixpoint of $T_P$ ($lfp T_P$).
  - $H_P = T_P \uparrow \omega$.

  I.e., least model semantics ($H_P$) $\equiv$ fixpoint semantics ($lfp T_P$)

- In addition, there is also an equivalence with the operational semantics (SLD-resolution):
  - SLD-resolution answers “yes” to $a \in B_P \iff a \in H_P$.

- Because it gives us a way to directly build $H_P$ (for finite models), the least fixpoint semantics can in some cases also be an operational semantics (e.g., for datalog in deductive databases).
